

Weather Database

Instructions

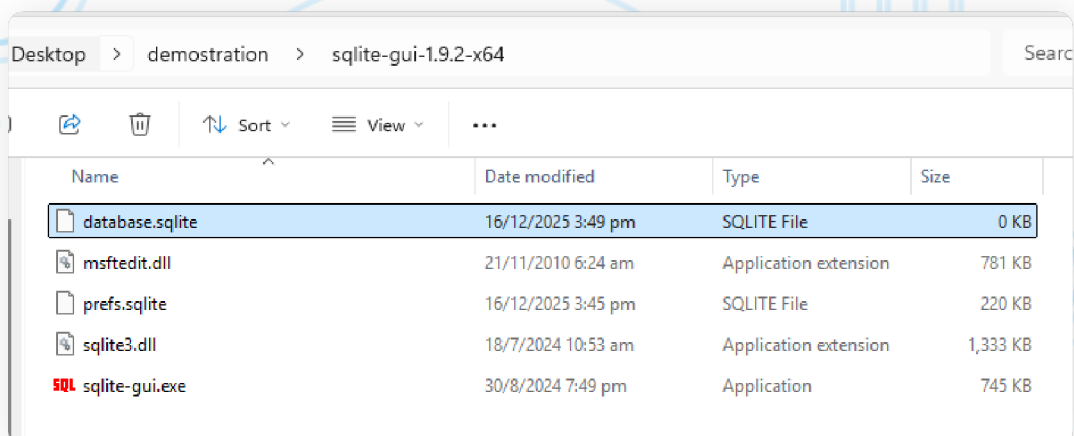

1. Continue with the same server as previous exercise, but rename it to `weatherdatabase_server.py`.

2. Remove the JSON files and replace them with a single SQLite database file **database.sqlite**: 1) Extract attached **sqlite-gui-1.9.2-x64.zip** and run the program 2) Hit 'Cancel' when asked to create a demo database

- 3) Create a new database in file **database.sqlite** in same directory as server

- 4) Open **database.sqlite** in the program

4) Add a new table 'cities', with columns 'city' (text), 'temperature' (integer), 'humidity' (integer), 'description' (text)

Add table

Name >>

Columns

#	Name	Type	PK	NN	UQ
1	city	text	v		
2	temperature	integer			
3	humidity	integer			
4	description	text			
5					

☐ Strict match of value type to column type

5) Right click the new table and click "Edit data"

6) Add a row per city with its corresponding values.

Table CITIES [4 rows]

name	temperature	humidity	description
london	18	60	Partly cloudy
paris	22	55	Sunny
new york	20	70	Cloudy
tokyo	25	80	Rainy

3. Change the server code to query the database when serving a user request. Look into python's sqlite3 package

- [SQLite Python Library Documentation](#)
- [SQLite Tutorial](#)

4. Reminders 1) The network protocol should be case insensitive (sending "london" and "LONDOn" should produce the same result). 2) Adding a city in runtime (this time not by creating a new file, but by adding a DB row with the sqlite-gui) should work without restarting the server 3) The network protocol must not change (in other words, the same old client will seamlessly work with the new server)

To submit

Submit ZIP of server directory which includes `weatherdatabase_server.py` and the database file `database.sqlite`.
